**A B S T R A C T**

This review aims at studying the phytochemistry and biological activities of some selected Apocynaceae plants. Eleven members of this family were reviewed for their phytochemistry and biological activities. Interestingly, the commonly isolated compounds reported from *Mondia whitei* (Hook.f.) Skeels, *Secondatia floribunda* A. DC, *Carissa carandas*, *Tabernaemontana divaricate*, *Nerium oleander*, *Wrightia tinctoria*, *Tabernaemontana divaricate*, *Alstonia scholaris*, *Carrisa spinarum Linn*, *Thevetia peruviana* and *Caralluma lasiantha* were triterpenoids, flavonoids, phytosterols, cardiac glycosides and lignans. All of them exhibited remarkable biological activities, mostly similar to each other. This review provides a detailed insight into the pharmacological activities of these selected members of this family.

**ARTICLE INFO**

**Article Type:** Mini Review

**Article History:**
- Received: 12 April 2019
- Accepted: 21 June 2019

**Keywords:** Phytochemistry, Biological activities, Medicinal plants

**Implication for health policy/practice/research/medical education:** This review provides a detailed insight into the pharmacological activities of Apocynaceae plants and showed that selected members of this family can be used as a reliable source for preparation of new drugs.

**Introduction**

The plants used for medicinal purposes are known to be potential sources of therapeutics and play important role in our daily life (1,2). In developing nations, medicinal plants are used as alternative source of treatments (3) whereby the extracts and phytochemicals isolated from them have shown *in vitro* and *in vivo* biological activities (4).

Mankind has used herbal products to treat pains and to even cure different forms of ailments (4) for the past 60,000 years (5). Presently, over 50 % of natural drugs that are being used for medication, are derived from plants (5,6).

The World Health Organization (WHO) has reviewed that about 80% of the population all over the world use herbs to treat various ailments (7) as well as for their other healthcare needs (2).

Herbals are natural products that have been found to be safe because of the limited side-effects. Apart from the medicinal uses of these herbals, they are also used as dietary supplements assisting the human body as defensive mechanism against these diseases. These days, herbal products are being sold in powder form, tablets, capsules and tea extracts (4). Traditionally, herbal products are seen to be harmless to people; they do not hesitate to take them without any prescription and in any dosage. However, some of these plants may be toxic and can cause grave health problems. However, some that are taken may not be effective and some may even interact with other drugs used. Assessing the quality and standard of these herbal products is very important so as to determine the bioactive ingredients that confers on them these huge medicinal potentials (8). This review provides a detailed insight into the pharmacological activities of these selected members of this family.

**The Apocynaceae family**

Apocynaceae family (also called the dogbane family) includes flowering plants which are made up of herbs, shrubs, trees, stem succulents and vines (5). The origin of members of this family were traced to the Europe, Asia, Africa, Australia, and American tropics or subtropics, with some temperate members (9). The former family called Asclepiadaceae (and now Asclepiadoideae) is considered to be a subfamily of the Apocynaceae which contains 348...
Many of these species are mainly the tall trees found in tropical forests. However, some members grow in tropical dry areas while some members are perennial herbs found in temperate zones. Many of these plants are known to have milky latex while some species of the family are known to be poisonous if ingested. For instance, *Adenium* a genera of the Apocynaceae family have been reported to have a milky latex while *Pachypodium* have only clear sap without latex.

Major characteristic features of this family are that almost all species are known to produce milky sap. Ethnomedicinally, the Apocynaceae family is being used to treat malaria, gastrointestinal ailments, fever, pain and diabetes as well as skin infections.

plants is given in Table 1.

**Phytochemistry and biological activities of Apocynaceae family**

Biological assays have been done on *Mondia whitei* (Hook.f.) Skeels including anti-inflammatory, anti-tyrosinase, antimicrobial, anti-aphrodisiac and antioxidant activities (8). The qualitative phytochemical analysis of ethanol extract of *M. whitei* led to the isolation of propacin, coumarinolignan, 5-clopropacin, (-)-loliolide, 2-hydroxy-4-methoxybenzaldehyde and isovanilin (12).

A methylene chloride extract of *Mondia whitei* (Hook.f.) Skeels yielded various compounds including 2-hydroxy-4-methoxybenzaldehyde and 3-hydroxy-4-methoxybenzaldehyde (isovanillin) (11,13). The chemical

**Figure 1.** Chemical structure of some compounds isolated from selected Apocynaceae plants.
structure of some compounds isolated from selected Apocynaceae plants are given in Figure 1.

The phytochemical investigation of the ethanol extract of the stem bark of Secondatia floribunda A. DC (Apocynaceae) showed antibacterial activity clinically significant against strains of Staphylococcus aureus and Escherichia coli (13). The compounds isolated from this extract were gallic acid, caffeic acid, cianidin, apigenin, catechin and quercetin (7,13).

Also, rutin, epicatechin, quercetin and kaempferol were isolated from Carissa carandas fruits as principal flavonoids with the total flavonoid content of 4.8 mg/100 g (1). The root and stem extracts of Tabernaemontana divaricata were also reported to contain novel flavonoids, calycosin and formononetin (1). All of these flavonoids exhibited anti-inflammatory potential against croton oil-induced edema in an albino mouse model with IC_{50} of 500 μg/mL (1,11).

Triterpenoids, lupeol, betulenic acid, oleanolic acid, α-amyrin and β-amyrin were largely distributed in the leaves, roots, and fruits of the Carissa genus (15). A novel oleanic acid isolated from Nerium oleander exhibited anti-inflammatory and anticancer potential (4,11). Phytochemical investigation of Wrightia tinctoria led to the isolation of a new triterpenoid, wrightial, and known lupeol (4). Taraxasterol acetate was isolated from the roots and stem of T. divaricata (4,11). Alstonic acids and oleanolic acid were reported from the leaves of Alstonia scholaris. These triterpenoids exhibited antitumor, antimicrobial and anti-inflammatory activities (15). Oleanolic acid exhibited anti-inflammatory activity against proinflammatory mediators such as nitric oxide (NO), tumor necrosis factor-α (TNF-α), and interleukin-1b (4,16).

Bioactivities exhibited by phytosterol include anti-inflammatory, heptaprotective and antihyperlipidemic activities (11). Wrightia tinctoria and Alstonia scholaris contain various kinds of phytosterols such as stigmasterol, β-sitosterol, and campesterol. Also, uncommon sterols, phytosterol and lanosterol were reported from Wrightia tinctoria seeds. Sitosterol glucoside was isolated from Carissa carandas roots. Stigmasterol from Carissa carandas has shown marked anti-inflammatory activity (4,14).

Carinol, carissanol and (−)-nortrachelogenin were isolated from the root extract of Carissa carandas (15).

A cardiac glycoside, kaneroside was isolated from the leaves of Nerium oleander (21). Cardiac glycosides were also isolated from the roots of Carissa carandas (4) and identified as odoroside and evomoside (19). Thevefolin was reported as a cardenolide of Thevetia peruviana. Thevefolin was reported to be effective for TRAIL resistance in human gastric adenocarcinoma cells (20).

Caralluma lasiantha has been studied for its phytochemical potential and the crude extract led to the isolation of luteoline-4-O-neohesperidoside and 3β,14β-dihydroxy-14β-pregn-5-en-20-one which exhibited antibacterial activity against both Gram (-) bacteria and Gram (+) bacteria (21).

**Conclusion**
The Apocynaceae plants have been reported for their vast medicinal potentials. In this study, eleven members of the Apocynaceae plants were reviewed for phytochemical constituent and biological properties. The most important phytochemicals commonly isolated from these plants were triterpenoids, flavonoids, phytosterols, cardiac glycosides and lignans. These phytochemicals were reported to exhibit similar biological activities. We also noted that all of them possess a wide range of biological properties. The ethnomedicinal uses of the Apocynaceae plants in treatment of various kinds of ailments might probably be due to these bioactive constituents.

**Authors’ contributions**
AE prepared the manuscript while authors RGA, JDH and HI supervised the research. All authors contributed equally in planning and carrying out this study. All authors read the manuscript and confirmed the publication for final version.

**Conflicts of interest**
No conflicts of interest among the authors.

**Ethical considerations**
Ethical issues have been observed by the authors.

**Funding/Support**
This study receives no funding or grant.
